

Coin Heist

Team members:

- Wendy Zhang Huang
- Taylor Pearce

Game expanded:

- Stealth Game from Assignment 4

Summary of all additions and changes:

- Added two additional levels
- Collectible system
- Button to unlock the door
- Lasers
- Flashlight
- Main Menu
- Credits

Description of Graphics:

- We implemented visual enhancements to improve the atmosphere of the game. We added a global volume with post-processing effects to create a darker and more suspenseful environment that fits the bank heist theme. We applied color adjustments and vignette effects to reduce the brightness of the scene. We also tweaked the overall environment lighting to make it darker. We also added some point lights to the objects, so players could see them. And with the help of bloom effect, the lights are more appealing and easy to catch.

Audio assets:

- Button Audio
- Music Audio
- Coin Collected Audio
- Laser Audio

Reflection:

- Taylor Pearce: For this project I designed and implemented the levels, the sound effects and music, and created the logic for the player, the button, and the door. A large issue I was experiencing was having the button and door logic work in tandem to transition between scenes. It was hard to have these two aspects intertwined because they used different scripts but I was able to solve this by using very simple trigger logic and the built in SceneManager. It was also quite difficult to properly visualize how I wanted each

level to be. We wanted to keep the theme of a bank heist but it was hard to do that without just making a big empty room. I countered this by making the maps reminiscent of a laser tag arena with obstacles placed sporadically throughout each level which I think came out quite nice. This project gave me a better understanding of map design and how to make levels flow well.

- Wendy Zhang Huang: For this project I contributed to some of the mechanics such as collectible coins and lasers. I also worked on the guard AI system and integrated visual effects and post-processing to improve the atmosphere of the game. I also implemented the UI showing objectives to guide players through the game. One of the biggest challenges was debugging the guard detection system and trigger events. I moved a lot of the mechanics from Assignment 4 to this project and made sure everything was implemented correctly, but for some reason the guards weren't detecting the player. Later I discovered that the guards' raycasts were detecting the ground instead of the player, which prevented the detection system from working properly. When trying to fix this problem, I learned how Unity's layer system works. This is how I gained a better understanding of raycasting and how layers can be used to control interactions between game objects.
